OVERVIEW

Introduction

Nereum is a Layer 1 blockchain with real-world asset tokenization built into the protocol: property, private credit, debt, invoices and funds issued, governed and settled directly on the network.

Nereum Finance LLC, registered in **Miami, Florida**, is the company behind it.

The problem

Most of the world's value sits in assets that cannot be moved with any agility. Not for lack of demand, but because the process that transfers them is still manual.

Every transaction requires verifying that the buyer meets the conditions attached to the asset — jurisdiction, investor category, holding period — reviewing the documentation and updating a private register. That work is done by a person, on business days, and charged by an intermediary on every transfer.

The result is a market where settlement takes weeks and the asset is valued once a year rather than priced continuously.

What tokenization adds

Tokenization represents the right over that asset as a record on a public chain: readable at any time, transferable in seconds, with a history that does not depend on the bookkeeping of any single institution.

This is already done on general-purpose chains. The limitation is not in representing the asset, but in where its rules are enforced.

What makes Nereum different

When an asset with transfer restrictions is issued on Ethereum, BNB Chain or Solana, the token lives on the chain but **the policy governing it lives outside it**. The network validates the signature and the balance; compliance is resolved in a separate system, after the transfer has been recorded.

That forces correction after the fact: reversing transactions, reconciling registers or, at worst, accepting that a restricted asset ended up with a holder who did not qualify.

On Nereum the policy is part of the asset and is evaluated during transfer validation itself. The conditions are bound at issuance and accompany the asset through every subsequent transfer. The network checks the eligibility of sender and recipient in the same step in which it checks the balance and the signature.

If any condition is not met, the transfer **does not settle**. There is no intermediate state to reverse, because it was never written.

What it solves

CURRENT MODEL	ON NEREUM
Settlement in days or weeks	Atomic settlement in seconds
Compliance verified after the fact by a third party	Verified by the protocol before recording
Intermediation cost on every transfer	No manual verification per transaction
Periodic valuation	Continuous, auditable on-chain price
Private register, opaque to the holder	Public register, readable without permission
The rule can be lost when the asset changes venue	The policy travels with the asset

Position relative to other networks

Other networks target real-world assets, some with considerable funding and track record. The relevant difference is not announced volume, but **which layer each one places compliance in**.

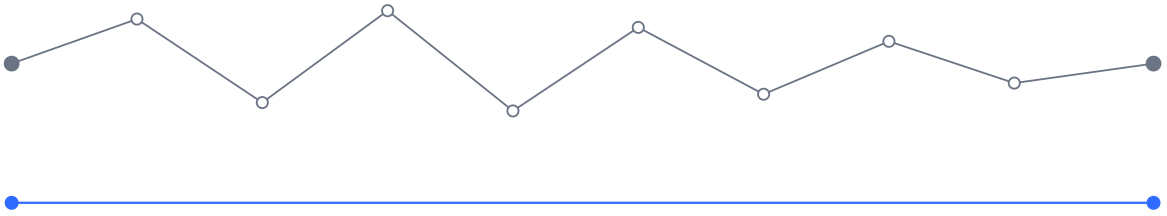

Most implement it as an application layer on an existing chain. Nereum implements it in the protocol. That is the more expensive decision — it requires building consensus, validators and tooling from scratch rather than deploying a contract — and it is what makes it possible to guarantee that the rule applies on every transfer, in every venue, for the life of the asset.

What backs this project

ITEM	WHERE TO VERIFY IT
Company registration Nereum Finance LLC · Miami, Florida · registered	See Legal Document — Miami, FL
Team KYC CyberScope · verified · certificate issued 14 October 2026	See Team KYC
Contract audit CyberScope · completed · 6 of 6 checks passed	See Audit

Where to start

If you read three pages, read the vision, the legal document and the audit. The last two are the ones any discerning reader checks first.

The same transfer: many manual steps above, one settled step below

OVERVIEW

Vision

To place Nereum among the most widely used real-world asset tokenization protocols, by being the network where issuing, governing and settling a regulated asset is technically simpler than on any alternative.

The market it addresses

Real-world assets — property, private credit, corporate debt, commercial paper, fund interests — generate yield continuously and transfer with a friction that has not meaningfully decreased in decades.

The consequence is not only operational. An asset whose transfer takes weeks carries an illiquidity discount in its valuation. **Reducing that friction does not merely accelerate the transaction: it changes what the asset is worth.**

The technical basis

Nereum's thesis is that compliance belongs in the protocol rather than in an application layer above it.

That decision allows an instrument with transfer restrictions to circulate with the properties of a native token — atomic settlement, deterministic finality, continuous availability — without giving up the conditions that make it compliant.

The rest of the infrastructure is built on that base: a block explorer, a policy-aware native exchange, a stable settlement asset, an issuance engine that requires no bespoke development, vaults for aggregated exposure, and a data and attestation layer that maintains the link between a token and its documentation.

None of those components is incidental: each covers a requirement without which the network is not usable end to end.

Adoption phases

PHASE	WHAT IT COVERS
Foundation	The token contract deployed, verified and audited by CyberScope, the company registered in Florida and the team KYC verified by CyberScope. Each step is checkable by someone who is not us.
Expansion	The chain and the interfaces that sit on top of it, built and out in the open, with a price anyone can look up.
Integration	The infrastructure ceases to be a decision factor for the issuer, in the same way interbank payment rails are not one today.

Foundation IN PROGRESS

- ✓ Development of the entire NRM ecosystem
- ✓ Contract deployed
- ✓ Code verified on Etherscan
- ✓ Company registered in Florida · Nereum Finance LLC
- ✓ Contract audit completed · CyberScope
- ✓ Team KYC verified · CyberScope

Expansion IN PROGRESS

- ✓ Development of the Nereum Blockchain infrastructure
- ✓ Development of the Assets Tokenization interface
- ✓ Development of the online BTC mining interface

Those are the phases by what is built in each. What each one has to *prove* for adoption is a separate question, and the answer does not change with the calendar:

- One asset class issued entirely on Nereum and transferred between qualified holders with no human intervention in the settlement path.
- Tokenized assets accepted as collateral. An asset reaches genuine liquidity when credit is available against it.
- The infrastructure ceases to be a decision factor for the issuer, in the same way interbank payment rails are not one today.

Impact by participant

Issuers

Policy is defined once, at issuance, and the protocol enforces it permanently. Distributing the asset no longer requires legal review on every transfer.

Holders

Ownership that is independently verifiable and transferable without settlement windows. A fractional interest acquires the operational behaviour of a listed security.

Markets

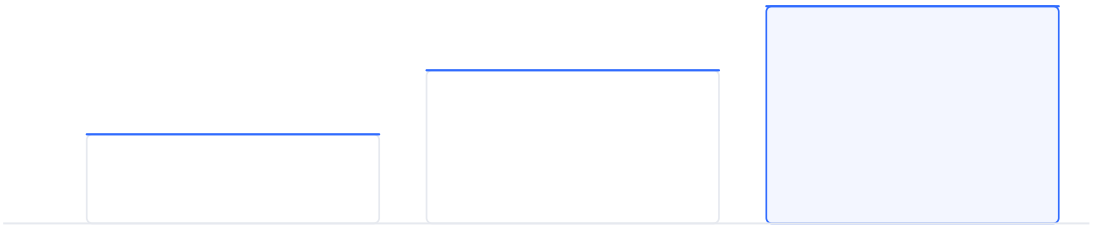

Assets with periodic valuation gain a continuous price, which enables collateralized credit, composite portfolios and secondary markets with measurable depth.

The basis of the proposition

Other projects compete for the same market and several hold an advantage in capital and schedule. The differentiating factor is not who arrived first, but the layer at which each resolves compliance.

Building a complete Layer 1 requires more resources than deploying a contract on an existing network. In return it provides a guarantee that cannot be added afterwards: **that the policy is inseparable from the asset**.

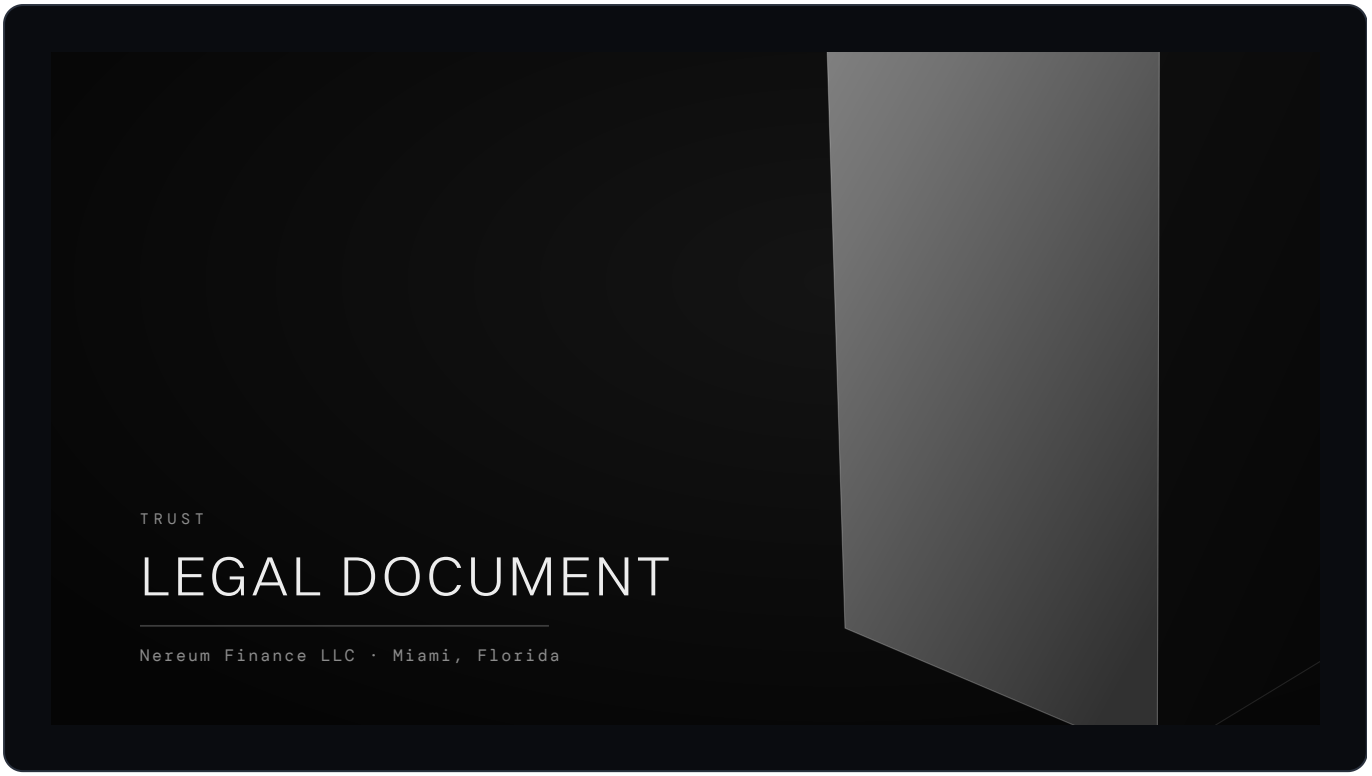

The stated objective is not leadership by volume, but to constitute the technically obvious option for issuing a real-world asset on-chain.

Each phase only begins when the previous one is live

TRUST

Legal Document — Miami, FL

A blockchain project asks strangers to send money to an address. The least it owes them in return is **a legal person with a name, an address and a public filing** — one that anyone can look up without permission, without an account, and without taking our word for anything.

Nereum is operated by **Nereum Finance LLC**, a limited liability company **registered in Miami, Florida, United States**. The filing was approved by the Florida Division of Corporations, and its certificate of status can be downloaded from the state's own website with tracking number **6697114960CU**.

Because it is filed, there is a named entity, subject to a jurisdiction with functioning courts, that can be contacted, held to its public statements and sued if it breaks them. It is not a guarantee of anything. It is the floor below which a serious project should not operate.

The filing

ITEM	VALUE
Legal name	**Nereum Finance LLC**
Entity type	Limited Liability Company
Jurisdiction	Miami, Florida, United States
Document number	**L26000497769**
Certificate of status	Tracking no. **6697114960CU**
Verification link	Sunbiz · certificate authentication
Status	**Registered**

Verify it yourself, in four steps

Florida keeps a free public business registry. You do not need us for any of this, and we would rather you did it than believed us:

1. Open the **Florida Division of Corporations** search (sunbiz.org), the state's official registry.
2. Search by the entity name, or paste the document number listed above.
3. Confirm three things match what is written here: the exact legal name, the document number and the current status.
4. Open the annual reports on the record. A company that files on time is a company that is still being run by someone.

OFFICIAL VERIFICATION

The registration of Nereum Finance LLC can be verified at the source, without relying on us. Go to the certificate authentication service of the Florida Division of Corporations (Sunbiz), the State's official business registry, and enter tracking number **6697114960CU**. It returns the certificate of status issued by the State of Florida, confirming that the company is on record and showing its current status.

Who stands behind the entity

A company is only as accountable as the people named on it. The founder is verified by a third party, CyberScope — see Team — so the entity is not a shell with nobody attached.

Together the filing and the identity verification answer the two questions a careful reader actually has: *does this thing exist legally*, and *is there a person who can be found if it goes wrong*.

A named entity in a jurisdiction, verifiable in a public register

TRUST

Audit

An audit is an independent review of the contracts by a firm with no stake in the outcome. It is the only part of a project's security that an outsider can evaluate directly — which is why it carries so much weight, and why an audit badge with nothing behind it is worse than no badge at all.

This page holds the review, the deployed addresses, and the reason both matter: **Nereum has no owner**. Once the code is running, nobody — including us — can change it. That makes the audit the last line of defence rather than one of several.

The audit is **complete**. **CyberScope** reviewed the NRM token contract — **Nereum.sol**, deployed on Ethereum — and issued its report on **6 October 2026**. The contract passed **all 6 checks** in the analysis, with no critical or medium findings and **a single minor/informative note**, explained below.

The review

ITEM	VALUE
Firm	**CyberScope**
Status	**Completed**
Full report	PDF in CyberScope's public repository
Report on the auditor site	app.cyberscope.io/audits/nrm
Scope	The NRM token contract: **Nereum** (`Nereum.sol`). The Seed Round sale contract is not part of this report; it has not been deployed yet.
Audited address	`0x9eAb4Ab3D08d0cAc72ACAcEA19904aF2f0D69228` · Ethereum
Compiler	`v0.8.30+commit.73712a01` · optimization at 200 runs
Code reviewed	SHA256 of the `Nereum.sol` source file, as stated in the report: `692aa74a20ad4dae285b13517147926406f32b549ce7bacf096cff03e5eedb4a`
Date	6 October 2026 · *Initial Audit*
Checks	**6 of 6 passed**
Findings	0 critical · 0 medium · 1 minor/informative
Finding status	Acknowledged by the team — see the note
Re-audit after fixes	Not applicable: the report has a single version, and its only note is informative and was acknowledged without code changes

OFFICIAL VERIFICATION

The report can be verified at the source, without relying on us. Open the public audit page on CyberScope's website and check that the audited address matches, character by character, the deployed contract: `0x9eAb4Ab3D08d0cAc72ACAcEA19904aF2f0D69228`. The original PDF is also in CyberScope's public audit repository on GitHub.

The six checks

The analysis in the report runs six checks on the contract, and the contract passed all of them:

- ✓ **ST** · Stops Transactions — passed
- ✓ **OTUT** · Transfers User's Tokens — passed
- ✓ **ELFM** · Exceeds Fees Limit — passed
- ✓ **MT** · Mints Tokens — passed
- ✓ **BT** · Burns Tokens — passed

✓ **BC** · Blacklists Addresses — passed

The informative note

The report contains a single note, of minor/informative severity: **ROF · Redundant Ownable Functionality** (`Nereum.sol#L724`). It points out that the contract inherits `Ownable` and defines an owner, but that owner has no administrative functions: it can only transfer or renounce ownership, with no privileges over supply, transfers, allowances or fees.

The team acknowledged it and explained in the report itself why it was kept: the owner was retained only so that ownership could be **renounced on-chain**, as public proof. Saying a contract has no owner is not the same as proving it with a renunciation event, and ownership was renounced — check it on Etherscan.

Nobody owns this

Nereum is built to belong to the people who hold it — its community and its investors — not to the team that wrote it. That is a design decision with consequences, and every part of it is verifiable on-chain:

PROPERTY	WHAT IT MEANS	CHECK
Fixed supply	160,000,000 NRM at genesis. No mint function that anyone can call, ever.	Etherscan ↗
No pause	Transfers cannot be frozen. Not by us, not by anyone.	Etherscan ↗
No blacklist	No address can be blocked by decree.	Etherscan ↗
Governance	How protocol decisions are made, and by whom.	`Pendiente · governance model`

Deployed contracts

Every deployed address on a public explorer, so the code that was audited and the code that is running can be compared line by line.

ITEM	VALUE
Token	**NRM**
Contract address	`0x9eAb4Ab3D08d0cAc72ACAcEA19904aF2f0D69228`
Chain	**Ethereum** · ERC-20
Verified source	View on Etherscan ↗
Ownership	**Renounced** — view the transaction ↗

How to read an audit report

Most people look at the number of findings. That is the least useful part. Four things matter more:

1. **The commit hash.** An audit reviews one specific version of the code. If the deployed contract does not match the audited commit, the report describes software that is not running. This is the single most common way an audit badge misleads.
2. **The scope.** Which contracts were in, and which were left out. A review of the token says nothing about the sale contract.
3. **The open findings.** Every report has some. What matters is which were accepted as risk, and the reasoning given.

4. **The date.** Code changes. An audit from before the last deployment is history, not assurance.

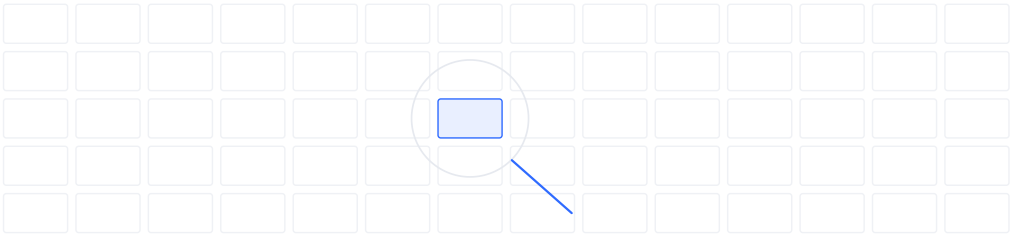

Why the audit matters more here

On a project where the team keeps admin keys, a bug can be patched. That is a safety net, and it is also a back door — the same key that fixes a bug can drain a treasury.

We gave up that key ↗. It means **no insider can act against holders**.

What an audit cannot tell you

- Whether the economics of the project make sense.
- Whether the team will do what they said with the funds raised.
- Whether a bug exists that the reviewers did not find. Usually one does.
- Whether the contract deployed afterwards matches the one reviewed — that is what the commit hash is for.

An independent review reads the deployed code, line by line

TRUST

Team KYC

The KYC is **complete**. **CyberScope**, an independent security firm, verified the identity of the founder of Nereum and issued the **KYC certificate on 14 October 2026**: a firm that is not us has seen government identification for the person running this project and holds it on file.

ITEM	DETAIL
Provider	**CyberScope**
Status	**Verified**
Certificate date	14 October 2026
KYC certificate	certificate in CyberScope's public repository
CyberScope page	app.cyberscope.io/audits/nrm — *Fundamentals* tab

KYC certificate issued by CyberScope for Nereum ($NRM) · 14 October 2026 · view the original on GitHub

> **OFFICIAL VERIFICATION**
> The KYC can be checked at the source, without relying on us. Open the certificate CyberScope publishes in its public KYC repository on GitHub, or the Nereum page on CyberScope, where the audit and the KYC are listed.

It is not a badge we bought to decorate a page. It is a name and a face on record with someone who is not us, and who can be compelled to produce them.

Why this matters in a funding round

Most projects raising money at this stage are run by people you cannot name. That is normal in crypto and it is not automatically bad — plenty of serious software has shipped anonymously.

But it changes what happens when something goes wrong. **An anonymous team that disappears leaves nobody to pursue.** There is no jurisdiction, no subpoena, no case. The money is simply gone, and the only recourse is a thread on social media.

What makes this uncommon

Team KYC on its own is not rare. Plenty of Seed Rounds advertise a verification badge, and there are several firms that issue them.

What is less common is the **full set** — and each part covers a gap the others leave open:

PROOF	WHAT IT ANSWERS
Company registration	Does a legal entity exist, in a jurisdiction with courts? Legal Document — Miami, FL
Team KYC	Is there a real, identified person behind that entity?
Contract audit	Has the code been reviewed by someone independent? Audit

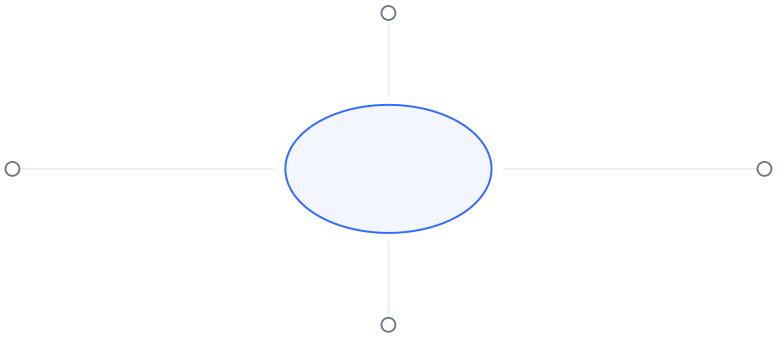

A company without named people is a shell. Named people without an audit is trust in strangers. An audit without renounced ownership leaves the back door open. **The four together are what accountability actually looks like**, and each one is verifiable without asking us for anything.

What is verified, and what stays private

Verification does not mean the founder's documents are published. The firm holds the identification; the public sees a certificate confirming it was checked.

- **The firm sees** government identification, and typically runs a liveness check and sanctions screening.
- **The public sees** that verification was completed, by whom, and when.
- **Authorities can see** the underlying identity, if legally compelled through the firm.

That balance is the point: accountability without publishing a passport on the internet.

Four proofs around one centre: none of them works alone

TOKEN

Join the Seed Round

The Seed Round is the pre-listing allocation: the window in which NRM is sold before it trades on the open market, at a fixed price set by the project.

The Seed Round is open at **nereum.xyz** and nowhere else. Every other channel is listed on Official links.

The token

ITEM	VALUE
Symbol	**NRM**
Network	**Ethereum** · ERC-20
Total supply	**160,000,000** — fixed at genesis, cannot grow
Buy / sell tax	**0%**
Seed Round price	**$0.20**
Price at listing	**$1.00** — Uniswap v3 liquidity
Contract	Ownership renounced — view the transaction ↗

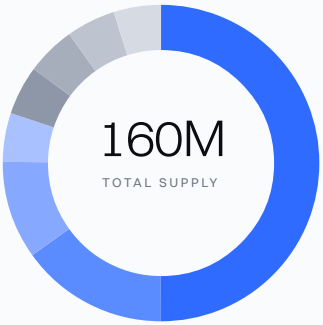

Terms of the round

ITEM	VALUE
Minimum	**$1**
Maximum per wallet	**$10,000**
Target	**$16,000,000**

What this round gives you

FEATURE	WHAT IT MEANS FOR A BUYER
Entry at $0.20	The lowest price the project will sell at. NRM opens at $1.00 on Uniswap v3, where the opening price is set by the pool's range.
$1 minimum	Deliberately low. A round that starts at four figures is a round designed to exclude most people.
$10,000 cap per wallet	Limits how much of the round one buyer can take, which keeps the holder base wider and the post-listing sell pressure less concentrated.
Fixed supply, 0% tax	What you buy cannot be diluted by new minting, and no fee is taken from your transfers.
Renounced contract	After you buy, nobody can pause transfers, blacklist your wallet or change the rules — including us. See the renouncement ↗

Distribution of supply

Seed Round	50.0%	80,000,000
CEX listing	15.0%	24,000,000
Marketing	10.0%	16,000,000
Reserve	5.0%	8,000,000
Team · locked	5.0%	8,000,000
Advisors	5.0%	8,000,000
Development	5.0%	8,000,000
Airdrop	5.0%	8,000,000

ALLOCATION	SHARE	TOKENS
Seed Round	50.0%	80,000,000
CEX listing	15.0%	24,000,000
Marketing	10.0%	16,000,000
Reserve	5.0%	8,000,000
Team · locked	5.0%	8,000,000
Advisors	5.0%	8,000,000
Development	5.0%	8,000,000
Airdrop	5.0%	8,000,000

Use of funds

What the money raised is spent on, and in what proportion.

A raise without a stated use of funds asks buyers to trust an intention they were never told.

How to take part

1. Go to **nereum.xyz** and type the address yourself rather than following a link from a message.
2. Connect a wallet you control. Never a seed phrase — no legitimate sale asks for one, ever.
3. Check the contract address on the page against the one on Official links, character by character. The first and last four are not enough.
4. Choose an amount between $1 and $10,000 and confirm.

We do not send private messages, we do not run a support account that contacts anyone, and we do not announce sales anywhere other than the addresses listed on Official links.

How to read this page

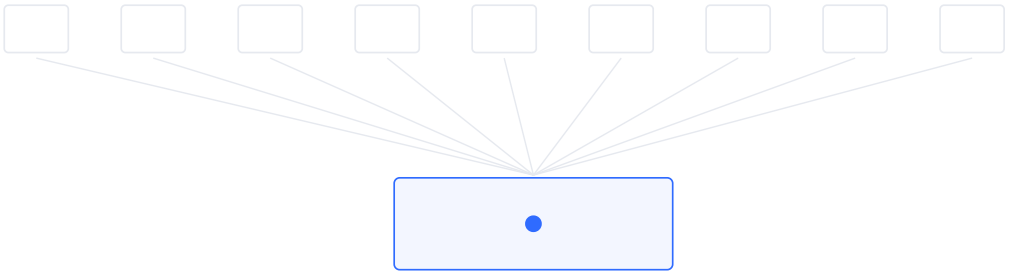

Two numbers decide whether the rest of it means anything:

1. **The raised figure** has to be the on-chain amount, linked to an address anyone can open. A raise number that cannot be checked does more damage than no number at all.
2. **The vesting schedules.** Half the supply released on day one and half released over four years are completely different projects with identical pie charts.

How the listing price is set

NRM lists at **$1.00 on Uniswap v3**. That price is not an estimate: on Uniswap v3, liquidity is concentrated within a price range chosen when the pool is created, so **the opening price is a parameter of the pool**.

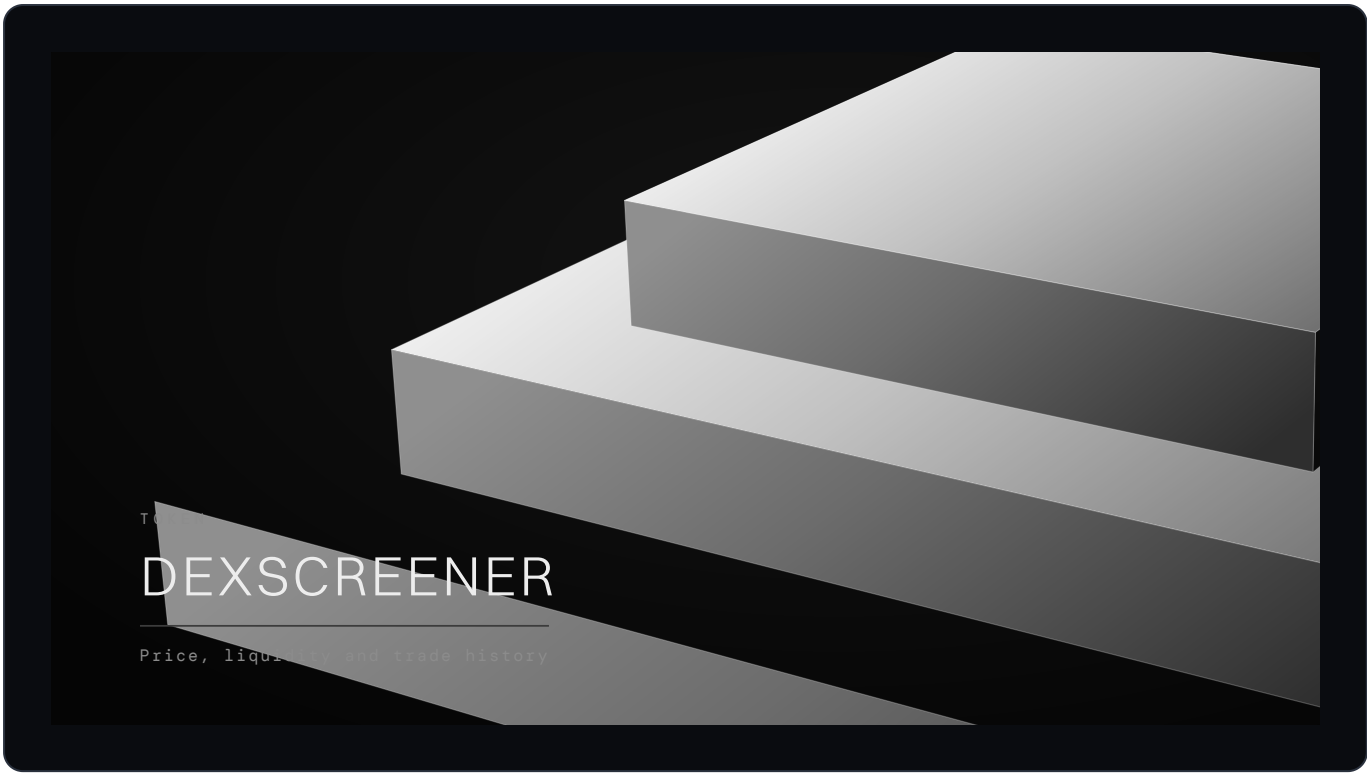

ITEM	VALUE
Venue	**Uniswap v3** · Ethereum
Liquidity	**Uniswap v3 liquidity**, concentrated in the range chosen when the pool is created
Opening price	**$1.00**

Many participants, one allocation, one published cap per wallet

TOKEN

DexScreener

Where the NRM price, liquidity and trade history can be tracked once the token is trading — by anyone, without an account.

The pair

ITEM	VALUE
Token	**NRM**

What to look at, in order

Price is the least informative number on the screen. Four things tell you more:

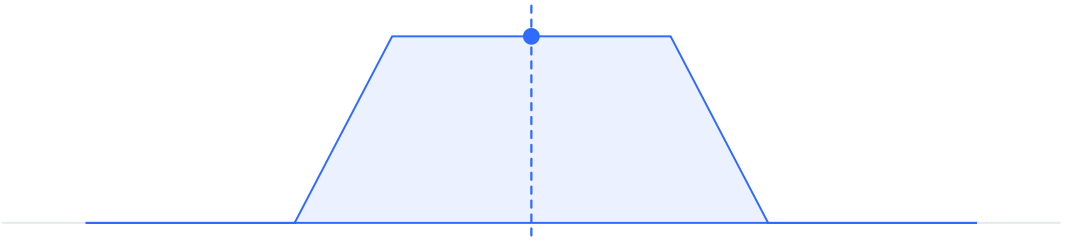

1. **Liquidity, and whether it is locked.** A pool that can be withdrawn at any moment is not liquidity, it is a promise. Look for the lock and its expiry date.
2. **Holder concentration.** If a handful of wallets hold most of the supply, the price on screen is whatever they decide it is.
3. **Age of the pair.** When it was created, and by whom. A pair created hours ago has no price history worth reading.
4. **Volume against liquidity.** High volume in a thin pool is usually the same funds going back and forth.

Verify the address before you trade

Anyone can create a pair and name the token whatever they like. DexScreener lists what exists, not what is legitimate.

The only contract that is ours is the address listed on this page and on Official links. **If a pair does not match that exact address, it is not NRM** — no matter what the ticker says, how convincing the chart looks or who sent you the link.

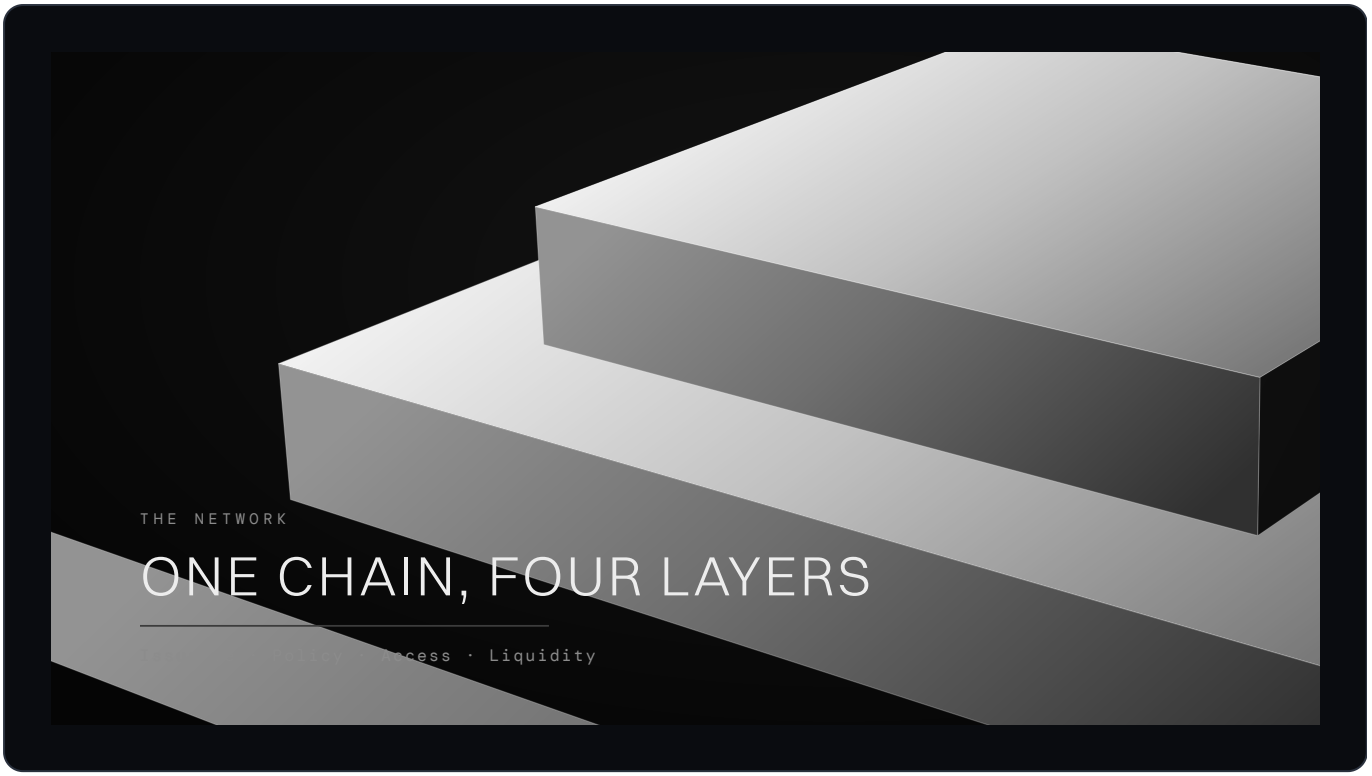

Until the token trades

Depth concentrated around the opening price

PROTOCOL

NereumEVM — Blockchain

This is the chain itself: the machine that decides what gets written and what does not.

It is a complete blockchain: its own validators, its own consensus, its own token and its own state. It is EVM-compatible, so it runs standard smart contracts and any developer who has built on Ethereum can build here without learning anything new.

Where it departs from every other network is in what it checks. All of them verify that a signature is real and that a balance exists. NereumEVM verifies a third thing — whether this holder may receive this asset — and it asks the asset, because here **an asset is not only a balance: it carries the conditions its issuer attached to it.**

What that means in practice

An issuer tokenizes an asset directly on the chain: the property, the loan, the invoice. When it is created, it carries the conditions that govern it — which jurisdictions may hold it, which class of holder qualifies, any holding period, what has to be reported.

From then on those conditions travel with the asset. Every time it changes hands, the network checks them as part of validating the transfer, in the same step and at the same speed as it checks the balance and the signature.

That is why this had to be a chain and not an application. A rule deployed on top of a network can be routed around — move the asset to a venue that does not run your contract and the rule stops travelling with it. A rule the validators enforce cannot be left behind, because there is nowhere on this network where it does not apply.

One chain, four layers

Every asset issued on Nereum passes through all four, every time it moves.

01	Issuance	What exists, and under whose authority

02	Policy	The conditions that travel with it
03	Access	Who may hold and move it
04	Liquidity	Where it can be exchanged

01 · Issuance

Creates the on-chain record and binds it to what exists off-chain — a deed, a note, an invoice. It records the issuer, the authority under which they issue, a reference to the underlying document, and the policy set that will travel with the asset from that moment on.

02 · Policy

The conditions that must hold for a transfer to settle: jurisdiction, holder class, lock-up, reporting. Attached to the **asset**, not to the wallet holding it — which is why they survive every transfer, every venue and every change of owner.

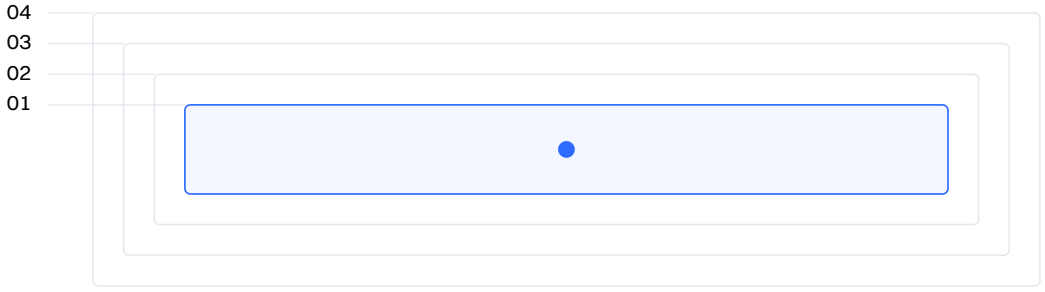

03 · Access

Who may hold and move an asset, checked on **every** transfer rather than once at onboarding. Holders prove eligibility with verifiable credentials from an approved issuer: the chain checks the credential, not the person behind it.

Controlled visibility works the same way — a counterparty sees what the policy allows and no more.

04 · Liquidity

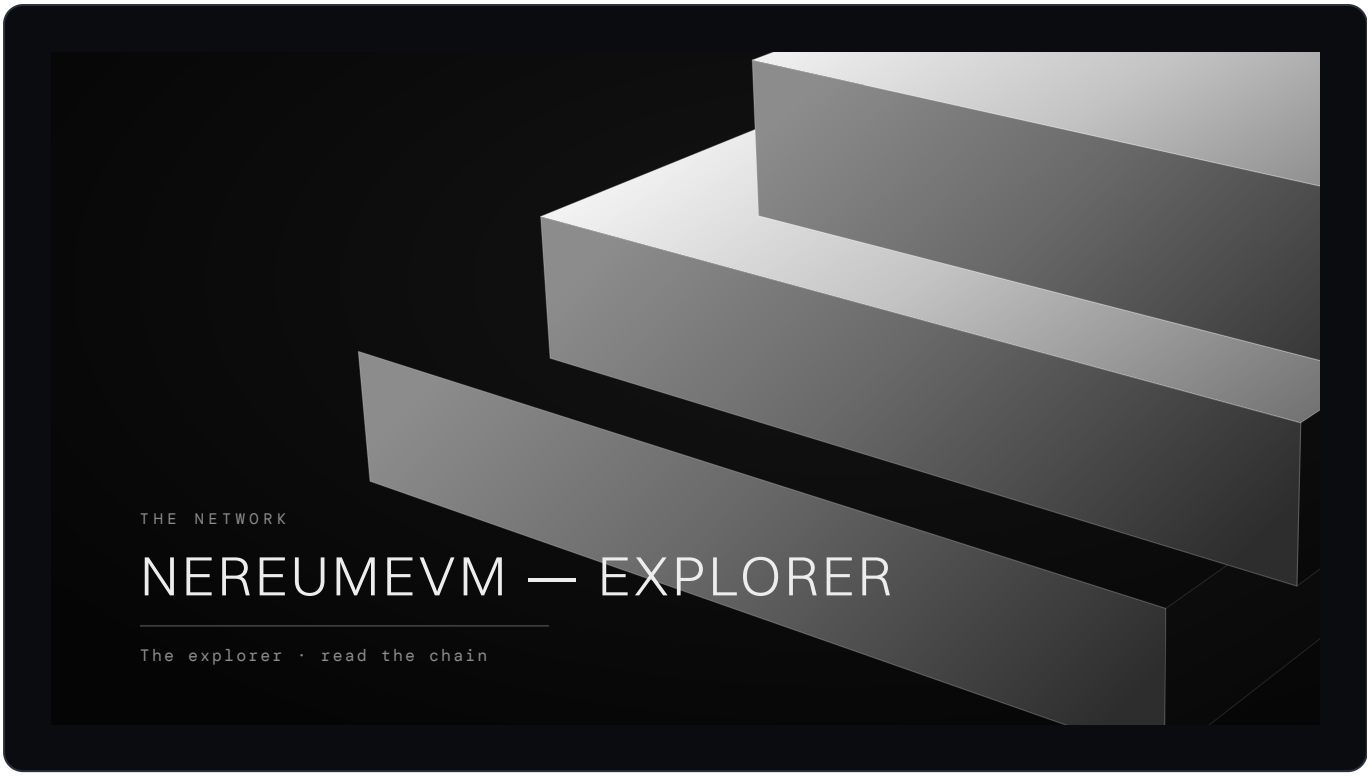

Where the asset can be exchanged, and under what constraints. Covered below.

Four layers around the same asset, checked on every transfer

PROTOCOL

NereumEVM — Explorer

NereumEVM Explorer is the network's block explorer: a public website at **nereum.xyz/explorer** ↗ that reads the chain and shows what is on it — every block, every transaction, every address and every deployed contract.

What it shows

Open any address and you see its full history: what it holds, what it has sent, what it has received, and when. Open a contract and you see its verified source code, so the program that is running can be compared line by line with the code the team published.

For a tokenized asset it also shows what a general-purpose explorer cannot: the policy attached to the asset, how many qualified holders it has, and the document reference it was issued against.

How it works

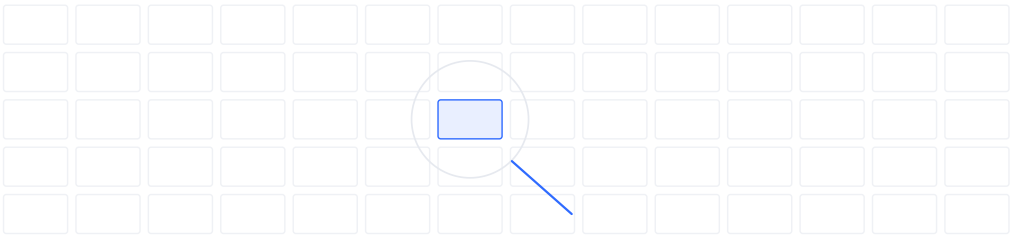

NereumEVM Explorer runs its own copy of the chain and indexes every block as it is produced. It does not have privileged access and it does not hold anything: it reads the same public data any node reads, and organises it so a person can use it.

That is why it can be replaced. If NereumEVM Explorer disappears tomorrow, anyone can run their own explorer against the same chain and see exactly the same thing.

The problem it solves

A blockchain without an explorer is a database nobody can read. The data is public in theory and unreachable in practice, because reading it directly means running a node and writing software.

NereumEVM Explorer is what turns *"you can verify this yourself"* from a claim into an instruction. Every proof in this document — the supply, the contract, the ownership, the holders — ends at an address someone has to be able to open. NereumEVM Explorer is where they open it.

Every block open to anyone, with no account and no permission

PROTOCOL

Asset tokenization

Tokenizing an asset is not hard. Making it **move**, and keeping it enforceable while it moves, is the whole problem.

The issuance flow described on this page is open now. Run it yourself at **nereum.xyz/explorer/#/tokenize** ↗: describe the asset, attach its documentation, choose the policy and issue.

This page is how an asset gets onto Nereum, what the chain records about it, and what happens when the on-chain record and the off-chain world disagree.

From asset to token

STEP	WHAT HAPPENS
01 · Origination	The asset and its documentation are established off-chain: title, valuation, the legal vehicle that holds it.
03 · Issuance	The on-chain record is created and bound to the document by reference and hash.
04 · Policy binding	The conditions are attached to the asset itself, not to the first wallet that holds it.
05 · Distribution	It reaches qualified holders, each checked at transfer time rather than once at onboarding.

The link to the real thing

A token representing a building is worth exactly as much as its link to the deed. Break that link and you have a number in a database.

Nereum records three things that keep it intact:

- **The reference.** Which document, held where, under which registry entry.
- **The hash.** A fingerprint of that document, so any later alteration is detectable.
- **The attestation.** Who vouched for the binding, when, and under what authority.

All three are on-chain. None of them requires trusting us: they are checkable by anyone with the document in hand.

Custody of the underlying

Nereum records the claim; it does not hold the asset. Something in the physical world still has to.

Life after issuance

Most tokenization projects describe issuance and stop. An asset lives for years after that, and the events that follow are where the design is really tested.

Income and distributions

Rent, coupons, repayments. Paid on-chain, proportionally, without a register being reconciled first.

Corporate actions

Revaluation, splits, changes to the terms. The record has to accept them without breaking the history that came before.

Redemption

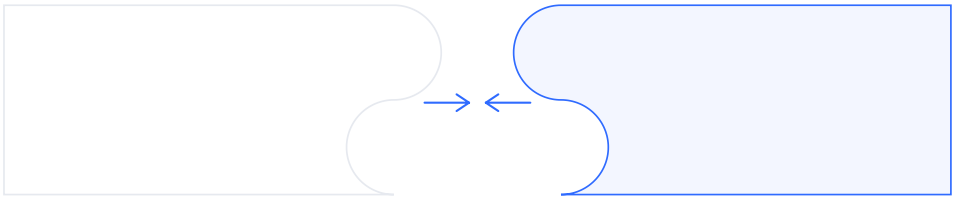

The asset is sold, matured or repaid, and the token has to be retired against it.

When the record and reality disagree

Every tokenization project is judged on this, and most whitepapers avoid it. The honest answer has three parts: what the protocol does automatically, what requires the issuer to act, and **what a court can compel regardless of what the chain says**.

What tokenization does not do

- It does not make an illiquid asset liquid. It removes friction; it does not create buyers.
- It does not replace the legal claim. The token points at it.
- It does not remove counterparty risk from the custodian or the issuer.
- It does not make a bad asset good. A tokenized bad loan is a bad loan that settles faster.

The document and the record, bound so neither moves without the other

PROTOCOL

Nereum DEX

Nereum DEX is the exchange built into the network: where tokenized assets are bought and sold, priced continuously and settled on-chain. The app is at nereum.xyz/app ↗.

What it does

- **Pair quotation.** Any listed asset trades against NUSD, NRM or another asset, with a price that updates on every trade rather than once a quarter.
- **Atomic settlement.** The asset and the payment change hands in the same transaction. Both legs or neither — there is no window where one side has delivered and the other has not.
- **Policy-aware routing.** An order that would end with the asset in a wallet that does not qualify is never matched in the first place.
- **Public price history.** Every trade is recorded on the chain, so an asset that used to be valued once a year has a continuous, auditable price.

How it works

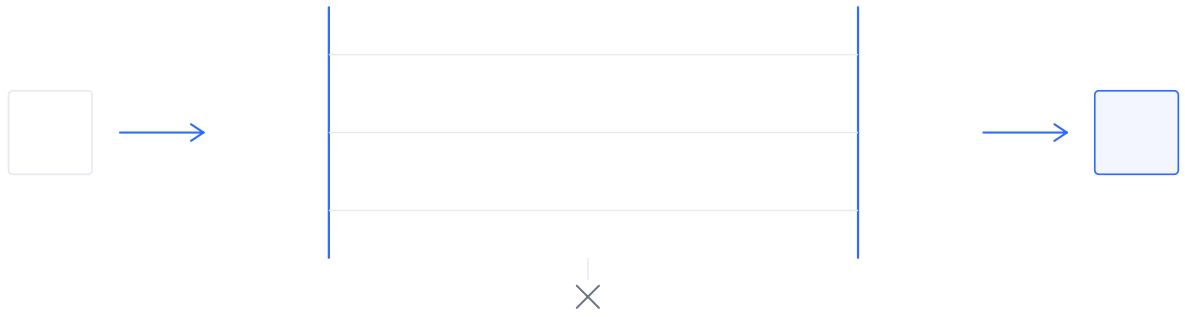

The exchange is part of the protocol rather than a contract deployed on top of it. When a trade is submitted, the same validation that checks the balance and the signature also checks the asset's policy — for both sides of the trade and for the liquidity pool itself.

That last point is the reason it has to be native. On a general-purpose chain, an asset with transfer restrictions and an automated market maker are in conflict: the pool has to hold the asset, and a pool is not a qualified holder. Projects work around it with wrappers and allow-lists. Here the pool is simply a participant like any other, and the rules apply to it the same way.

The problem it solves

A tokenized asset that cannot be traded is a certificate with extra steps. The whole argument for putting a building on a chain is that it becomes as transferable as a share — and that only happens if there is somewhere to transfer it.

The DEX is also what produces the price. An asset with no market has a valuation; an asset with a market has a price, and the difference matters to everyone who has to mark it, lend against it or sell it.

Only a transfer that satisfies the policy reaches the other side

PROTOCOL

NUSD

NUSD is the network's settlement asset: a stable unit, native to the chain, that the payment side of every trade is denominated in.

What it is

One NUSD is worth one dollar and is backed by reserves held off-chain. It behaves like any other token on the network — it moves in seconds, settles on-chain and can be held in any wallet — but its value does not move against the currency the underlying assets are priced in.

How it works

A holder acquires NUSD by depositing dollars or an equivalent stable asset with the issuer, who mints the corresponding amount. Redemption runs the same way in reverse: return the NUSD, receive the dollars.

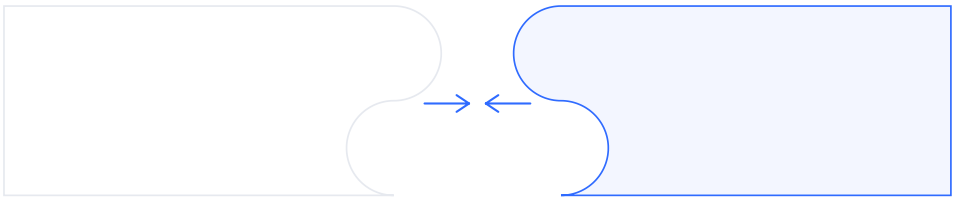

What makes a stablecoin credible is not its name but its reserve: what backs it, who holds it, who audits it, and how a holder redeems it at par. Those four answers belong in public before it circulates at scale.

The problem it solves

Delivery versus payment needs a payment leg. If someone sells a tokenized bond, the buyer pays with something — and for the two legs to settle in the same transaction, that something has to live on the same ledger.

Without a stable settlement asset on the chain, the payment happens somewhere else: a wire, an exchange, another network. The moment it does, the settlement stops being atomic, and the risk that one side delivers and the other does not comes straight back.

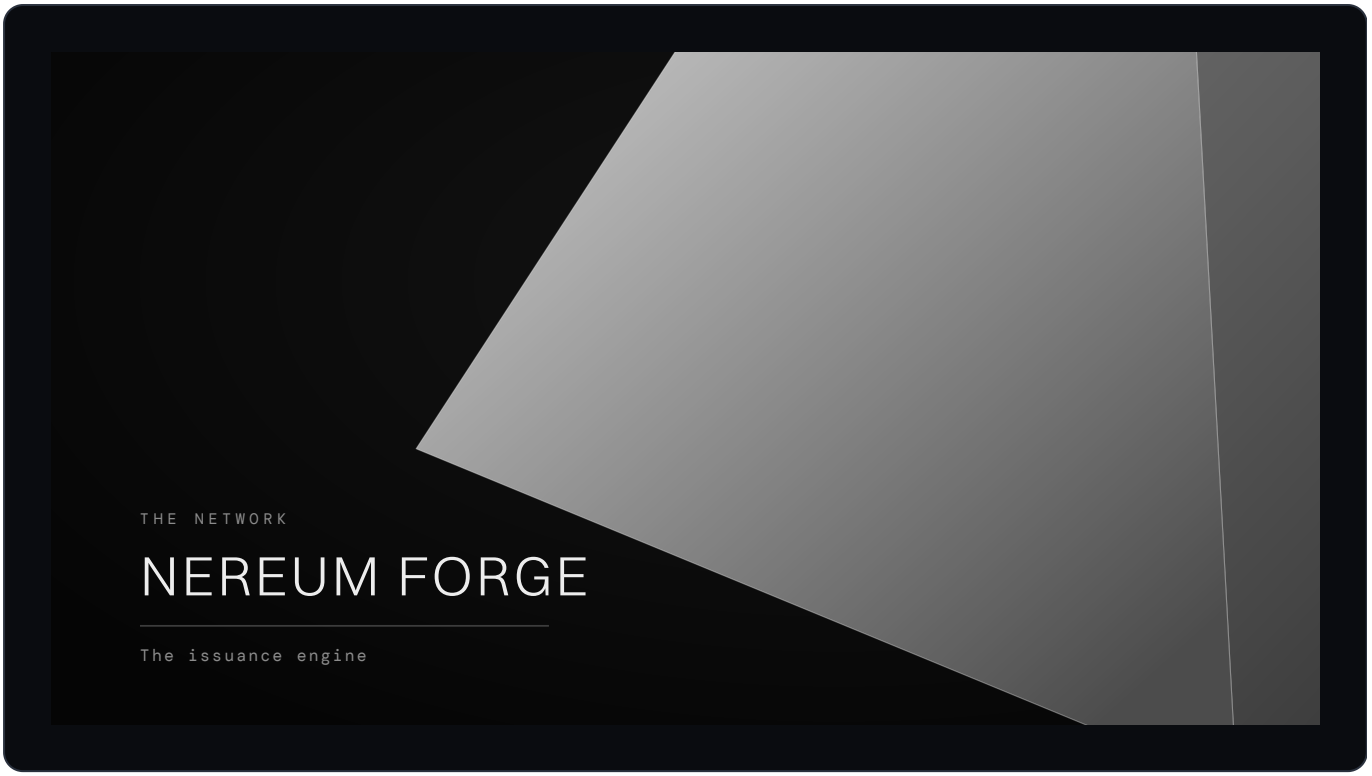

The alternative — settling in a volatile token — is worse. Nobody prices a five-year note in an asset that can move ten per cent while the transaction confirms. **NUSD is what makes atomic settlement mean something in practice**, rather than only in the architecture diagram.

Asset and payment settle as one movement, or not at all

PROTOCOL

Nereum Forge

Nereum Forge is the issuance engine: where an asset becomes a token without anyone writing a smart contract.

What it does

An issuer describes the asset, attaches its documentation, selects the conditions that must travel with it, and issues. What comes out is a token on the chain, bound to the underlying document and governed by the policy that was chosen at creation.

How it works

1. **Describe the asset.** What it is, who issues it, under what legal authority, and what vehicle holds it.
2. **Attach the documentation.** The deed, the note, the invoice. Forge records a reference to it and a fingerprint of the file, so any later alteration is detectable.
3. **Choose the policy.** Which jurisdictions may hold it, which class of holder qualifies, any minimum holding period, what has to be reported and to whom.
4. **Issue.** The token is created with the policy already attached. From that point the network enforces it on every transfer.

The problem it solves

Tokenizing an asset today means hiring someone to write and audit a custom contract for each issuance. That costs money and months, and it means every asset on the network behaves slightly differently, because every contract was written by a different person.

Forge replaces that with a described process. The same policy conditions are available to every issuer, they behave identically across assets, and they are enforced by the protocol rather than by whatever the contract author remembered to include.

This is the layer that decides whether the network gets used at all. A chain is infrastructure; **the issuance engine is what turns "we have a Layer 1" into "an issuer can list an asset on Tuesday"**.

The policy is stamped onto the asset at the moment of issuance

PROTOCOL

Nereum Vaults

Nereum Vaults are managed baskets of tokenized assets: deposit a stable asset, receive exposure to a portfolio held on-chain.

What they are

A vault holds a set of tokenized instruments — treasuries, private credit, invoices — and issues a token representing a share of the whole. The holder of that token is entitled to their proportion of whatever the underlying assets produce.

How they work

A holder deposits NUSD and receives vault tokens in return. The vault uses the deposit to acquire assets according to a published mandate: what it may hold, in what proportions, and under what limits.

Income from the underlying — rent, coupons, repayments — arrives on-chain and is distributed proportionally to vault token holders, without a register having to be reconciled first. To leave, a holder redeems the vault token or sells it on the DEX.

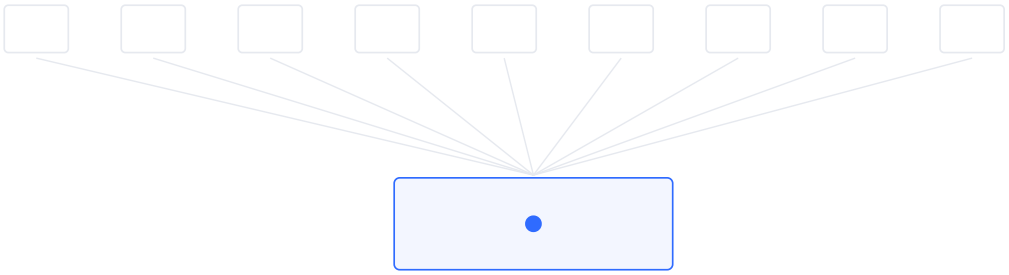

Everything the vault holds is visible on NereumEVM Explorer: the assets, the amounts and the movements. A vault is not a promise about a portfolio; it is a portfolio anyone can inspect.

The problem it solves

Real-world assets are hard for an individual to hold directly. Each one needs to be evaluated on its own terms — the borrower, the property, the counterparty — and the minimums are usually far beyond what a retail participant would commit.

The vault turns that into a single decision. Instead of underwriting a specific loan, a holder takes exposure to a diversified basket under a stated mandate, with the same on-chain visibility they would have over any other token.

It is also what gives the network a use for capital that is not institutional. Forge brings the issuers, and the vaults bring everyone else.

Many assets, one position, one published mandate

PROTOCOL

Nereum Feed

Nereum Feed is the data and attestation layer: what connects what happens in the world to what the chain knows.

What it carries

- **Valuations.** What an asset is currently worth, and who said so.
- **Reference prices.** Rates and benchmarks that instruments are priced against.
- **Corporate actions.** Revaluations, splits, amendments to terms, defaults.
- **Attestations.** Signed statements binding a token to the document behind it.

How it works

Data reaches the chain through approved providers who sign what they publish. The signature is the point: an entry on Feed is not an anonymous number, it is a statement by a named party who can be held to it.

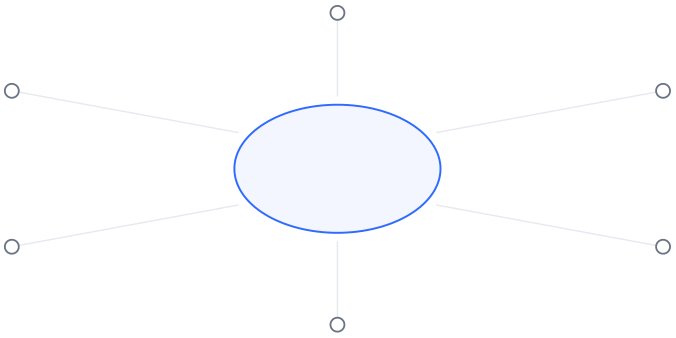

An attestation works the same way. When an asset is issued, a verifying party signs a statement that the documentation is what it claims to be. That signature stays on the chain, so the binding between token and document can be checked years later by someone who was not there.

The problem it solves

A token representing a building is worth exactly as much as its link to the deed. Break the link and what remains is a number in a database — technically sound, economically worthless.

Feed is what keeps the link intact and, more importantly, **auditable without trusting us**. Anyone can check who attested to what and when, and compare the document fingerprint on the chain with the document in hand.

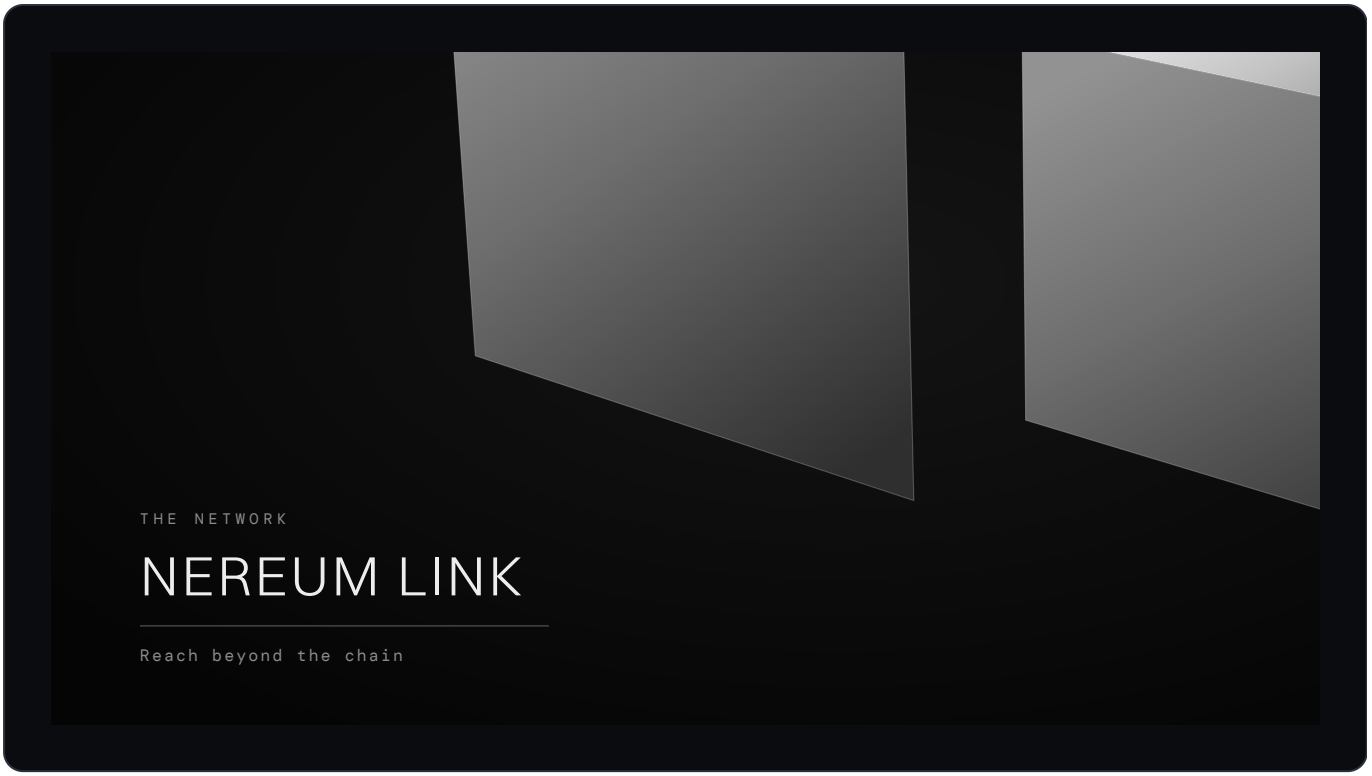

It is also what lets an asset stay current. A building revalued in March, a loan that goes into default in June — without a data layer none of that reaches the chain, and the record slowly stops describing reality.

Signed data from outside, converging on a single record

PROTOCOL

Nereum Link

Nereum Link distributes the yield of Nereum-native assets to holders on other chains, without the asset itself leaving the ledger where its rules are enforced.

How it works

The underlying asset stays on Nereum. What travels is a mirrored token on the destination chain that represents the economic exposure — the yield — rather than ownership of the asset.

Income produced on Nereum is routed to holders of the mirrored token wherever they are. The asset never moves, the policy never has to be interpreted by a chain that does not understand it, and the value locked stays where it is secured.

Why not a normal bridge

A standard bridge locks a token on one chain and mints a representation on another. For an asset with transfer restrictions, that representation arrives somewhere that knows nothing about its policy — and from that moment anyone can hold it, anywhere, regardless of what the original conditions said.

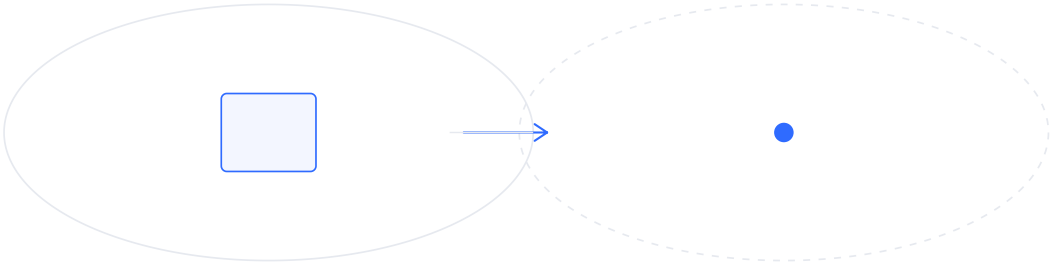

The compliance did not cross. Only the balance did. It is the most common way a compliant asset quietly stops being compliant.

Link is built the other way round: **the asset stays where the rules are, and only the economic exposure travels**.

The problem it solves

Most capital will never move to a new network. Someone holding stablecoins on Ethereum is not going to bridge, learn a new wallet and take on an unfamiliar chain's risk in order to earn a few points of yield.

Link removes that requirement. The holder stays where they are, in the wallet they already use, and the yield comes to them. For the network it means reach that does not depend on convincing anyone to migrate — which is the hardest thing a new chain has to do.

The asset stays in place; only the exposure travels

PROTOCOL

Wallet and tooling

The wallet holds credentials as well as assets, and the developer tooling lets anyone build on the network without asking permission.

The wallet

A normal wallet stores keys and balances. On Nereum a holder also needs to carry the credentials that prove they qualify to hold a given asset — issued by a verifying party, presented at transfer time, checked by the protocol.

The wallet stores those credentials alongside the assets and presents them automatically when a transfer requires it. The holder does not manage eligibility as a separate process; it travels with them.

This matters because of how the network is designed. Eligibility here is something a holder *proves*, not something an operator *grants* — and that only works if the holder actually has the proof in hand.

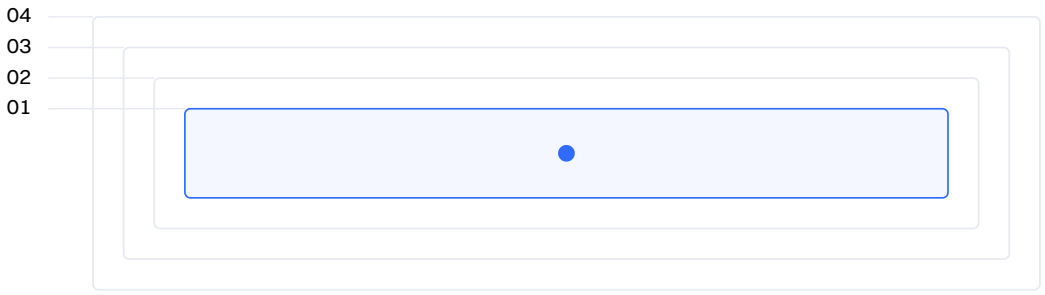

Developer tooling

- **SDK.** Libraries for issuing assets, reading policy and submitting transfers, so an application does not have to talk to the chain at the byte level.
- **Public documentation.** Every interface documented and readable without an account.
- **Testnet and faucet.** A full copy of the network with free tokens, so anything can be tried before it costs anything.
- **Public endpoints.** A way to read the chain and submit transactions without running infrastructure first.

The problem it solves

Networks that require a conversation before you can build on them do not get built on. A developer evaluating three chains on a Saturday will use the one whose documentation opens and whose testnet works, and will never contact any of the teams.

The tooling exists so that decision goes our way without anyone having to sell anything. And the wallet exists so the compliance layer, which is the whole point of the network, does not turn into paperwork for the person holding the asset.

Credentials travel with the holder, not with the operator

COMPANY

Team

Who is building Nereum, what they have built before, and what a reader can verify about them.

Core team

Eduardo Gut
FOUNDER & CEO

Strategy, capital and regulatory relationships. Signs on the treasury and answers for the entity registered in Miami.

Identity verification

KYC by a third party means someone independent has seen government identification for the people named above and holds it on file. It raises the cost of disappearing considerably. It does not vouch for competence, and it is not a background check unless the issuer says it is. For Nereum it was carried out by CyberScope and is complete: the certificate was issued on 14 October 2026.

Advisors

An advisor list is only worth including if each name comes with a specific contribution. Logos of people who attended one call do more harm than an empty section.

Named or anonymous

Both are defensible positions, and plenty of serious projects have shipped anonymously. What is not defensible is implying a named team exists without listing one.

If the team stays anonymous, this page should say so plainly and explain what stands in its place: locked contracts, funds in escrow, KYC held by a third party who can identify the founder to a regulator, or a multi-signature arrangement with named external parties.

Identity verified by an independent party and kept on file

COMPANY

News and mentions

Independent coverage of Nereum: articles, interviews and mentions published by someone other than us.

What counts as coverage

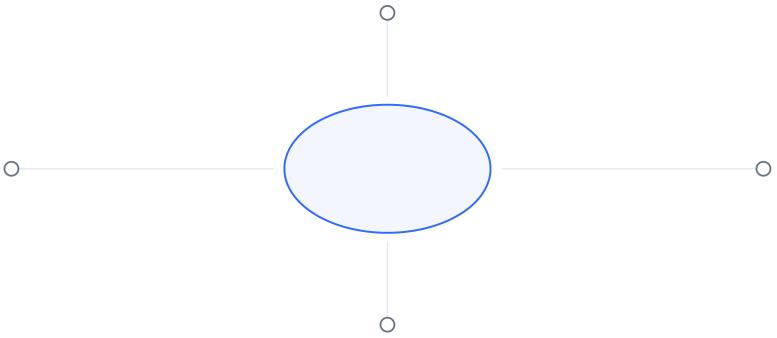

The distinction matters, because readers make it whether or not the page does:

- **Editorial coverage.** A journalist chose to write about the project. This is the only kind that carries independent weight.
- **Paid placement.** A press release distributed to syndication networks. Legitimate, common, and worth labelling as such — many outlets republish these automatically and they are easy to recognise.
- **Interviews and podcasts.** Useful, but the project chose what to say. Worth listing separately from editorial.
- **Aggregators and listings.** A database entry is not coverage.

Labelling each entry honestly costs nothing and buys credibility from exactly the readers who would otherwise check and find out.

Press kit

Making it easy for a journalist to write about you correctly is the cheapest communications work there is.

Independent coverage, separated from what the project chose to say

COMPANY

Official links

These are the only official addresses of Nereum. Anything not listed on this page is not ours, no matter how convincing the name, the logo or the person who sent it.

Impersonation is the most common attack on a project at this stage, and it requires no technical skill at all. A cloned site, a group chat one character off, a support account that messages first — every one of them works because people have nowhere authoritative to check.

This page is that place. Bookmark it.

Official channels

CHANNEL	ADDRESS
Website	nereum.xyz
Whitepaper	nereum.xyz/whitepaper
Explorer	nereum.xyz/explorer ↗ — where every claim in this document can be checked
Seed Round	nereum.xyz — the only place the round is open
X	x.com/nereuml1 — the only account we post from
Telegram	t.me/nereumfinance — the official group; the team never messages you first in private

Contract addresses

The only addresses that belong to NRM. A token with the same ticker and a different address is a different token.

ITEM	ADDRESS
NRM contract	`0x9eAb4Ab3D08d0cAc72ACAcEA19904aF2f0D69228` ↗ — the only address of the token
Network	**Ethereum** · ERC-20

How impersonation actually works

Five patterns cover nearly all of it. None of them is sophisticated, and every one of them still works:

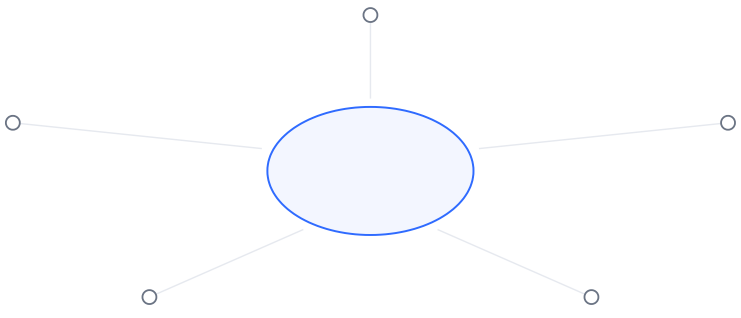

- **The support account that messages you first. We never do.** Not for help, not for verification, not to offer you an allocation. If someone contacts you claiming to be Nereum, that alone is the answer.
- **The domain one character off.** Look for swapped letters, an added hyphen, or a different ending — *.xyz* is ours. Read the address bar, not the text of the link.
- **The group chat with the same name.** Anyone can create one. Only the link on this page is ours.
- **The token with the same ticker.** Anyone can deploy a contract called NRM. Only the address on this page is ours.
- **The seed phrase request.** No sale, no wallet, no support agent and no legitimate project on earth needs your seed phrase or private key. There is no exception and no situation where this is normal.

Before you send anything, anywhere

1. Type **nereum.xyz** into the address bar yourself, rather than following a link you were sent.
2. Come back to this page and compare the contract address character by character. The first four and last four are not enough — address spoofing tools match exactly those.
3. Check the domain in the address bar, not the text of the link. Text can say anything.
4. If something is being rushed — a countdown, a closing allocation, a "last chance" — slow down. **Real deadlines survive you taking five minutes to verify.**

If you find a fake

Report it, and warn the people around you before you do anything else. A fake that gets taken down in an hour costs someone nothing; the same fake left running overnight costs someone everything.

One authorised centre; everything outside it is impersonation

COMPANY

Questions

The questions a careful reader actually asks, answered directly. Where the answer is not settled yet, it says so.

About the project

What makes this different from tokenizing on Ethereum?

On Ethereum the token is on-chain and the rules governing it are not. Here the rules are enforced by the protocol on every transfer, before settlement: if any check fails, the transfer never enters the ledger.

Who is the team?

Verified by a third party, CyberScope — see Team KYC — and operating through a company registered in Miami, Florida, which anyone can look up on the state registry.

About the token

Can more NRM be created?

No — and the reason is not a promise from us, it is how the machine works.

All 160,000,000 were minted once, when the contract was deployed. The code contains no function that creates new tokens. And the code of a deployed contract cannot be rewritten: it is fixed on chain exactly as published. A function that is not there cannot be added later — not by us, not by a future team, not by anyone who got hold of our keys.

There are two known ways around that, and neither applies here. The first is an upgradeable contract: a *proxy* that keeps the books in one place and fetches its code from another, so changing the second changes the rules. NRM is not a proxy; it is a plain contract. The second is a function reserved to the owner; ownership is renounced ↗ and the owner field is the zero address, so there is no address left for such a reservation to obey.

None of this has to be taken on trust. The source is verified on Etherscan and can be read in full, and the supply is visible on nereum.xyz/explorer ↗.

Is there a tax on buying or selling?

No. There is no fee function in the contract at all — not a fee set to zero that could be raised later.

Can my wallet be frozen or blacklisted?

No. A contract can only do what its code says, and the NRM code says nothing of the kind: there is no pause function, no blacklist, no whitelist, and no transfer hook that consults any list. A transfer checks two things — that the wallet holds the balance and, if a third party is moving it, that they have your allowance — and nothing else.

Since deployed code cannot be rewritten, such a function cannot be added later either. And ownership is renounced ↗: the owner field is the zero address, so there is not even a privileged address left to ask.

Put another way: freezing your wallet would take changing the code of a contract that can no longer be changed, on the orders of an owner who no longer exists. Check it on nereum.xyz/explorer ↗.

Where does NRM list, and at what price?

At $1.00, with Uniswap v3 liquidity. Because v3 concentrates liquidity in a chosen range, the opening price is a parameter of the pool. See Seed Round.

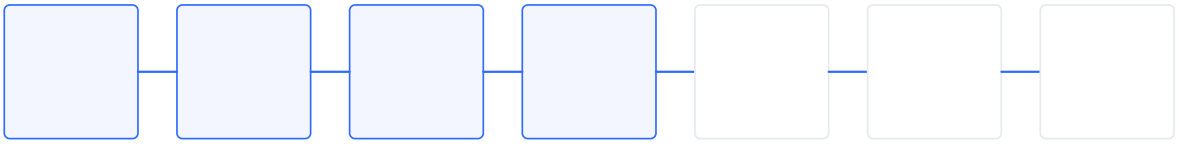

About taking part

How do I join the Seed Round?

At nereum.xyz, and nowhere else. Type the address yourself rather than following a link you were sent.

Will anyone from Nereum message me first?

Never. Not for support, not for verification, not to offer an allocation. Anyone who does is impersonating us — see Official links.

What is already final, and what is still ahead
